Arthroscopic Technique for Performing Remplissage using the HEALICOIL® PK Suture Anchor

Larry D. Field, MD
Arthroscopic Technique for Performing Remplissage using the HEALICOIL™ PK Suture Anchor

The following technique guide was prepared under the guidance of Larry Field, MD. Created under close collaboration with the surgeon, it contains a summary of medical techniques and opinions based upon his training and expertise in the field, along with his knowledge of Smith & Nephew’s products. Smith and Nephew does not provide medical advice and recommends that surgeons exercise their own professional judgement when determining a patient’s course of treatment. This guide is presented for educational purposes only.

Prior to performing this technique, or utilizing any product referenced herein, please conduct a thorough review of each product’s indications, contraindications, warnings, precautions and instructions as detailed in the Instructions for Use provided with the individual components.

Introduction

The shoulder is the most common joint to be traumatically dislocated, with a reported incidence of 11.2 per 100,000 annually. The incidence of Hill-Sachs lesions following a primary anterior shoulder dislocation is high, ranging in reports from 47% to 90%. The term, Hill-Sachs lesion, was coined after a 1940 report by Harold A. Hill, M.D. and Maurice D. Sachs, M.D. which detailed their experience with 119 cases of dislocated shoulders in which they identified a pathognomonic impaction fracture of the posterosuperolateral humeral head. This Hill-Sachs lesion was described in their report as a line of condensation on the internal rotation view of the humerus. Diagnosis of a Hill Sachs lesion is obtained either with advanced diagnostic imaging or dynamic arthroscopic assessment. Hill-Sachs lesions can create instability with patient apprehension in the affected shoulder, and lesions that prove to be associated with instability often involve either 25-30% of the humeral head or 5/8 of the radius of curvature, and are engaging with the anterior glenoid. In patients with these posterior humeral head defects, arthroscopic posterior capsulotenodesis with posterior capsule and infraspinatus, or Remplissage, is an arthroscopic procedure that can be utilized to supplement arthroscopic Bankart repair. The Remplissage procedure offers an effective and valuable technique for patients with certain Hill-Sachs lesions and has been demonstrated to reduce the risk of recurrent instability.
Patient Positioning / Portal Placement

It is the author’s preference to position the patient in a lateral decubitus position when managing Hill-Sachs lesions, although the procedure can be performed in the beach chair position as well if preferred. The patient is tilted posteriorly 30° to the vertical plane rather than “straight” lateral decubitus. The arm is then prepped and draped in sterile fashion and suspended in approximately 10-15 pounds of balanced suspension during the procedure. Standard arthroscopic portals are used and are further discussed below in the surgical technique.
Surgical Technique

The surgical technique is composed of 6 surgical steps, which includes a Bankart repair.

Step 1: Patient Set-up and Arthroscopic Assessment

1a. Set-up (Figure 1a)

The operative shoulder should be evaluated while supine on the operating room table for stability and range of motion while focusing on the position of the arm when the humeral head begins to engage or sub lux anteriorly to glenoid; this is compared with the contralateral extremity. The author prefers the lateral decubitus position for the patient, with the arm suspended in balanced traction and the shoulder tilted approximately 30 degrees posterior from the vertical plane thus improving access to the anterior shoulder during Bankart repair.

1b. Posterior Portal (Figure 1b)

Standard technique for posterior portal placement is used, placing the portal 2cm inferior and 2cm medial to the posterolateral corner of the acromion, in the soft spot.

1c. Diagnostic Arthroscopy (Figure 1c)

After portals are established, diagnostic arthroscopy is begun, paying close attention for the presence of a Hill-Sachs lesion while noting the size, location, and orientation.
1d. Dynamic Arthroscopic Assessment  
(Figure 1d)

The arm is then removed from traction for the dynamic assessment of the shoulder which should include taking the shoulder from the neutral position into external rotation at 0°, 45° and 90° of abduction, and an anterior drawer test is performed while the glenohumeral joint is viewed from the posterior portal.  
(Anterior portal can be used for dynamic assessment, as well). Engaging Hill-Sachs lesions are an indication to proceed with remplissage in addition to Bankart procedure. After completion of the dynamic assessment, a standard anterior portal is established using standard technique while viewing through the posterior portal.  

**NOTE:** A second more inferiorly located posterior portal may be required to adequately access the humeral head defect for anchor placement and suture passage later in procedure.

Step 2: Debridement (Figure 2)  

Debridement of the Hill-Sachs lesion must be performed for complete evaluation of lesion. Debridement is carried out with an arthroscopic shaver making sure to remove any unnecessary tissue present in the defect. This is performed through the posterior portal while viewing from the anterior portal. Debridement is also performed to help stimulate the bony bed to assist in healing of the soft tissues.
**Step 3: Anchor Placement (Figure 3)**

After debridement is performed, complete visualization of the Hill Sachs lesion is now possible and attention is taken to appropriate placement of anchors. One or two HEALICOIL® PK 5.5mm double loaded suture anchors are typically used by author, depending on the size of lesion. Anchors are placed immediately adjacent to articular cartilage of the posterior humeral head defect.

**Step 4: Suture Passing (Figure 4)**

With the use of a retrograde suture passer, all suture limbs are then passed sequentially from inferior to superior through the capsule and infraspinatus along the axis of Hill-Sachs Lesion. **All sutures used for the remplissage procedure are left untied until completion of the Bankart repair.**

**NOTE:** It is very important to complete Remplissage anchor placement and suture passage through to posterior capsule and infraspinatus prior to repair of the Bankart lesion since re-tensioning of the anterior ligamentous structures that occurs with Bankart repair results in significant posterior humeral head translation. This obligate posterior humeral head shift dramatically reduces the “working space” available to perform the Remplissage procedure within the posterior glenohumeral joint space adjacent to the Hill-Sachs lesion.

Step 5: Bankhart Repair (Figure 5)

After completion of posterior anchor placement and suture passing, 2 additional portals are made for the Bankart repair, the first including a mid-anterior portal, placed immediately superior to subscapularis tendon with an appropriate angle for placing anchors into the glenoid rim. The second portal is an anterior superior portal, which is used for viewing while a soft tissue elevator is inserted through the mid anterior portal and used to elevate and remove any scarred capsular or labral tissues that may inhibit adequate reattachment of the labrum. Typically, 3 or 4 SUTUREFIX Ultra double loaded suture anchors are used, depending on size of lesion, and spaced between the 5:30 and 1 o’clock positions and the 6:30 to 11 o’clock positions, for right and left shoulders respectively. Anchor placement and suture tying is started inferiorly and moved superiorly along glenoid rim. While passing suture limbs, they are placed in a more inferior position to corresponding anchor to help restore adequate tissue tension on the labrum. Often with the labral repair, the author includes anteroinferior capsular tissue when passing sutures providing a capsular imbrication as well as superior shift.

Step 6: Remplissage Suture Tying (Figure 6)

After completion of the Bankart repair, the Remplissage sutures are now tied while viewing from the anterior portal. This is performed by retrieving the sutures through a cannula in the posterior portal. After sutures are retrieved, they are blindly tied through the cannula but only after the cannula is advanced down to the infraspinatus fascia. Alternatively, direct visualization of suture tying can be performed by accessing the subacromial space and visualizing the process directly. The author prefers a sliding knot with 3 alternating half hitches for knot tying, and this is repeated with all suture limbs. After all sutures are tied, arthroscopic evaluation of glenohumeral joint stability is then performed to confirm appropriate glenohumeral joint balance and centering.
Postoperative Management

Patient is placed into sling with abduction pillow prior to leaving operative room. Rehab begins with passive pendulum exercises for first two weeks while maintaining active motion distally to shoulder, instructions given to patient to perform at home. At 2-6 weeks, formal physical therapy under supervision is begun and passive elevation to 90° with passive external rotation to 30° is added to the pendulum exercises already being performed. Strengthening at 2 weeks begins with scapular engagement exercises with assistance and education at therapy. Typically at 6 weeks, active motion is progressed in all patients with progression from isometric strengthening to more dynamic exercise including periscapular and rotator cuff strengthening. By 12 weeks, patients should have obtained full ROM and now begin functional strengthening in multiplanar positions. The author maintains and recommends a close working relationship with your physical therapist so patient protocols can be adjusted as needed.

### Indications for Use

**HEALICOIL™ PK Preloaded Suture Anchor**

**Shoulder**
- Bankart lesion repairs
- SLAP lesion repairs
- Acromioclavicular separation repairs
- Rotator cuff tear repairs
- Capsular shift or capsulolabral reconstructions
- Biceps tenodesis
- Deltoid repairs

**SUTUREFIX ULTRA Suture Anchor**

The SUTUREFIX ULTRA Suture Anchor is indicated for the secure fixation of soft tissue to bone for the following indications:

**Shoulder**
- Capsular stabilization
  - Bankart repair
  - Anterior shoulder instability
  - SLAP lesion repairs
  - Capsular shift or capsulolabral reconstructions
- Acromioclavicular separation repairs
- Deltoid repairs
- Rotator cuff tear repairs
- Biceps tenodesis
